Stochastic Elliptic Problems

Strong form: given \( f(x) \in L^2(D) \), find the stochastic function \( u(x,\omega) : \bar{D} \times \Omega \to \mathbb{R} \) such that for a.e. \( \omega \in \Omega \)

\[
\begin{aligned}
-\nabla \cdot (a(x,\omega) \nabla u(x,\omega)) &= f(x) \quad \text{in } D, \\
u(x,\omega) &= 0 \quad \text{on } \partial D,
\end{aligned}
\]  

where the coefficient \( a(x,\omega) \) could be, e.g., the permeability or conductivity field involving uncertainty.

\(\S\) Alexandra Foley, Can you use heat transfer to predict migration of contaminants?, COMSOL BLOG, 2013.
Existence and Uniqueness

Weak form: given \( f(x) \in L^2(D) \), seek \( u(x, \omega) \in H^1_0(D) \) such that

\[
\mathbb{E} \left[ \int_D a \nabla u \cdot \nabla v dx \right] = \mathbb{E} \left[ \int_D fv dx \right] \quad \forall v \in H^1_0(D),
\]

(2)

where \( H^1_0(D) = L^2(\Omega; H^1_0(D)) \) is the stochastic Sobolev space.

If the stochastic coefficient \( a(x, \omega) \) satisfies the integrability condition

\[
\frac{1}{a^\text{min}(\omega)} \in L^2(\Omega) \quad \text{and} \quad a^\text{min}(\omega) > 0 \quad \text{for a.e.} \ \omega \in \Omega,
\]

there exists a unique weak solution of (2), and the following estimate hold

\[
\| u \|_{H^1_0(D)} \leq C_D \left\| \frac{1}{a^\text{min}(\omega)} \right\|_{L^2(\Omega)} \left\| f \right\|_{L^2(D)},
\]

where \( a^\text{min}(\omega) = \min_{x \in \bar{D}} a(x, \omega) \) and \( C_D \) is the constant of Poincaré’s inequality.
Log-normal coefficient: \( a(x, \omega) = e^{g(x, \omega)} \) satisfies the integrability condition\(^\S\), where \( g(x, \cdot) \) is a zero mean Gaussian random variable with \( \text{Cov}_g(x, y) = \sigma^2 e^{-\frac{\|x-y\|}{\lambda}} \).

Truncated Karhunen-Loève expansion: \( g(x, \omega) = \sum_{m=1}^{M} \sqrt{\lambda_m} \phi_m(x) X_m(\omega) \), where the truncation number \( M \) is proportional to the smoothness of \( \text{Cov}_g(x, y) \).

\[
\text{Cov}_g(x, y) = 0.1 \times e^{-\frac{|x_1-y_1| + |x_2-y_2|}{0.2}} \text{ on } D = [0, 1]^2
\]
Grid-based representation\textsuperscript{§}: given \(\{x_i \in \bar{D}\}_{i=1}^{N}\) and positive-definite covariance matrix 
\(G_g = (\Cov_g(x_i, x_j))_{i,j=1}^{N} = \Theta \Theta^T\), then

\[
(a(x_1, \omega), \ldots, a(x_N, \omega))^T = e^{\Theta(X_1(\omega), \ldots, X_N(\omega))^T}, \quad X_i(\omega) \overset{iid}{\sim} N(0, 1).
\]

- GBR represents \(a(x, \omega)\) exactly on grid nodes while KLE with truncation error.
- The dimension of r.v.s in GBR varies w.r.t. mesh size while KLE stays the same.
- KLE is cheaper than GBR on fine meshes but more expensive on coarse meshes.

\[\text{Cov}_g(x, y) = 0.1 \times e^{-\frac{|x_1 - y_1| + |x_2 - y_2|}{0.2}} \quad \text{on} \quad D = [0, 1]^2\]

Concluding Remarks
Feedback control problems

Structure of SOCPs involves: state variables, control variables, an objective or cost functional and constraints.

SOCPs: find state and control variables \((u, f)\) that minimize (or maximize) the objective functional \(J(u, f)\) subject to the constraints \(G(u, f) = 0\) are satisfied.

\[\text{§} \text{M. D. Gunzburger et al. An algorithmic introduction to numerical methods for PDEs with random inputs, BCAM, 2013.}\]
Optimal Control Problem Governed by Elliptic SPDEs

Given a deterministic target function \( U(x) \in L^2(D) \), find the optimal robust control \( f^{\text{opt}}(x) \in \mathcal{A} \subset L^2(D) \) such that the objective functional

\[
J_{\beta}(u, f) = \mathbb{E}\left[ \frac{1}{2} \int_D |u(x, \omega) - U(x)|^2 dx \right] + \frac{\beta}{2} \int_D |f(x)|^2 dx
\]  

subject to the elliptic SPDE

\[
\begin{aligned}
-\nabla \cdot (a(x, \omega) \nabla u(x, \omega)) &= f(x) \quad \text{in } D, \\
u(x, \omega) &= 0 \quad \text{on } \partial D,
\end{aligned}
\]

is minimized. Our quantity of interest (QoI) is the expected value \( \mathbb{E}[u^{\text{opt}}] \).

Let \( \mathcal{A} \) be a closed convex subset, there exists a unique optimal solution pair \( (u^{\text{opt}}, f^{\text{opt}}) \in H^1_0(D) \times \mathcal{A} \) of the stochastic optimal control problem

Minimize (3) subject to state equation (1)\(^8\).

\( ^8 \) J. Lee, Analyses and Finite Element Approximation of Stochastic Optimal Control Problems Constrained by Stochastic Elliptic PDEs, Iowa State University, 2008.
For numerical implementation, we adopt following surrogate model with Monte Carlo approximation of problem (4) to realize a gradient-based optimization algorithm later:

$$
\text{minimize } \hat{J}_\beta(u, f) = \frac{1}{2N} \sum_{i=1}^{N} \int_D |u(x, \omega_i) - U(x)|^2 dx + \frac{\beta}{2} \int_D |f(x)|^2 dx \quad (5)
$$

subject to \( \begin{cases} 
\nabla \cdot (a(x, \omega_i) \nabla u(x, \omega_i)) = f(x) & \text{in } D \\
u(x, \omega_i) = 0 & \text{on } \partial D \end{cases} \quad \text{for } i = 1, \ldots, N, \quad (6)
\)

where our QoI \( \mathbb{E}[u^{\text{opt}}] \) is approximated by \( E_N[u^{\text{opt}}] = \frac{1}{N} \sum_{i=1}^{N} u^{\text{opt}}(x, \omega_i) \).

For any \( N \in \mathbb{Z}_+ \) and for \( u^{\text{opt}} \in \mathcal{H}_0^1(D) \) satisfying \( \frac{\partial \mathbb{E}[u^{\text{opt}}]}{\partial x} = \mathbb{E}[\frac{\partial u^{\text{opt}}}{\partial x}] \), there holds

$$
\|E_N[u^{\text{opt}}] - \mathbb{E}[u^{\text{opt}}]\|_{\mathcal{H}_0^1(D)} \leq \sqrt{\frac{C_D}{N}} \left\| \frac{1}{a_{\text{min}}(\omega)} \right\|_{L^2(\Omega)} \|f^{\text{opt}}\|_{L^2(D)}.
$$
Introducing the Lagrangian functional of problem (5-6),

\[ \mathcal{L}(u, f, \xi) = \widehat{J}_\beta(u, f) - \frac{1}{N} \sum_{i=1}^{N} a_i(u_i, \xi_i) + \frac{1}{N} \sum_{i=1}^{N} (f, \xi_i) \]

that defined for arbitrary \((u_i, f, \xi_i) \in H_0^1(D) \times \mathcal{A} \times H_0^1(D), i = 1, \ldots, N,\)

\[ (f, \xi_i) = \int_D f(x)\xi(x, \omega_i)dx, \quad a_i(u_i, \xi_i) = \int_D a(x, \omega_i)\nabla u(x, \omega_i) \cdot \nabla \xi(x, \omega_i)dx, \]

the equivalent system of problem (5-6) is given by: find \((u_i^{opt}, f^{opt}) \in H_0^1(D) \otimes L^2(D),\)

\(i = 1, \ldots, N,\) such that

\[
\begin{cases}
  a_i(u_i^{opt}, v_i) = (f^{opt}, v_i) & \forall v_i \in H_0^1(D) \text{ for } i = 1, \ldots, N, \quad \text{(state eqns)} \\
  a_i(\xi_i^{opt}, \zeta_i) = (u_i^{opt} - U, \zeta_i) & \forall \zeta_i \in H_0^1(D) \text{ for } i = 1, \ldots, N, \quad \text{(adjoint eqns)} \\
  (\beta f^{opt} + \frac{1}{N} \sum_{i=1}^{N} \xi_i^{opt}, z) = 0 & \forall z \in \mathcal{A}, \\
\end{cases}
\]

where our QoI is approximated by \(E_N[u^{opt}] = \frac{1}{N} \sum_{i=1}^{N} u_i^{opt}.\)
A Descent Direction for the Control Variate

Since the optimal solution of problem (5-6) satisfies
\[ \mathcal{L}(u^{\text{opt}}, f^{\text{opt}}, \xi^{\text{opt}}) \leq \mathcal{L}(u^{\text{opt}}, g, \xi^{\text{opt}}) \quad \forall g \in \mathcal{A}^{\text{§}}, \]
given \( f_{\text{old}} \), the descent direction could be constructed via the convex combination
\[ f_{\text{new}} = \epsilon g + (1 - \epsilon) f_{\text{old}} \quad \text{for some } \epsilon \in (0, 1) \text{ and } g \in \mathcal{A}, \]
such that \( \mathcal{L}(u_{\text{old}}, f_{\text{new}}, \xi_{\text{old}}) \leq \mathcal{L}(u_{\text{old}}, f_{\text{old}}, \xi_{\text{old}}) \). By letting \( \epsilon \to 0^+ \), we have
\[ \int_D (g - f_{\text{old}})(\beta f_{\text{old}} + \frac{1}{N} \sum_{i=1}^{N} \xi_{\text{old}}^{(i)}) \, dx \leq 0. \]

Then, by choosing \( g - f_{\text{old}} = -t(\beta f_{\text{old}} + \frac{1}{N} \sum_{i=1}^{N} \xi_{\text{old}}^{(i)}) \), we derive
\[ f_{\text{new}} = f_{\text{old}} - s(\beta f_{\text{old}} + \frac{1}{N} \sum_{i=1}^{N} \xi_{\text{old}}^{(i)}), \]
where \( s = \epsilon t > 0 \) is chosen to be a small stepsize.

Concluding Remarks
Multi-level Monte Carlo Method

Notations: suppose our QoI is $\mathbb{E}[Q]$ where $Q(x, \omega)$ solves a given problem, let $Q_\ell(x, \omega)$ denote the FE approximation of $Q(x, \omega)$ on mesh $\mathcal{T}_\ell$, and $Q^{(i)}_\ell(x)$ the corresponding realization $Q_\ell(x, \omega^{(i,\ell)})$ for $i = 1, \ldots, N_\ell$ and $\ell = 0, \ldots, L$.

Single-level Monte Carlo: given the mesh $\mathcal{T}_L$ and r.v.s $\{\omega^{(i,L)}\}_{i=1}^{N_L}$, SLMC gives

$$
\hat{Q}^{SL}_L = \frac{1}{N_L} \sum_{i=1}^{N_L} Q^{(i)}_L \text{ with } \|\text{MSE}(\hat{Q}^{SL}_L)\| \leq \frac{\|\mathbb{V}[Q_L]\|}{N_L} + \|\left(\mathbb{E}[Q_L] - \mathbb{E}[Q]\right)^2\|.
$$

Multi-level Monte Carlo: given meshes $\{\mathcal{T}_\ell\}_{\ell=0}^L$ and r.v.s $\{\omega^{(i,\ell)}\}_{i=1, \ell=0}^{N_\ell,L}$, MLMC gives

$$
\hat{Q}^{ML}_L = \frac{1}{N_0} \sum_{i=1}^{N_0} Q^{(i)}_0 + \sum_{\ell=1}^{L} \frac{1}{N_\ell} \sum_{i=1}^{N_\ell} (Q^{(i)}_\ell - Q^{(i)}_{\ell-1}),
$$

with $\|\text{MSE}(\hat{Q}^{ML}_L)\| \leq \frac{\|\mathbb{V}[Q_0]\|}{N_0} + \sum_{\ell=1}^{L} \frac{\|\mathbb{V}[Q_\ell - Q_{\ell-1}]\|}{N_\ell} + \|\left(\mathbb{E}[Q_L] - \mathbb{E}[Q]\right)^2\|$. 

Qi Sun | BCSRC & USTC
Instead of generating all realizations on one fixed mesh, MLMC uses hierarchical meshes

$$
\mathbb{E}[Q] = \mathbb{E}[Q_0] + \sum_{\ell=1}^{L} \mathbb{E}[Q_\ell - Q_{\ell-1}] + (\mathbb{E}[Q] - \mathbb{E}[Q_L]).
$$

Alternatively, one could use quasi-Monte Carlo, collocation rule, etc., for the numerical approximation of expectations.

**Notations:** let $Q_{-1} := 0$, we define $V_\ell := \| V [Q_\ell - Q_{\ell-1}] \|$ and $C_\ell$ the computational cost to obtain a single realization $Q_{\ell}^{(i)} - Q_{\ell-1}^{(i)}$ for $\ell = 0, \ldots, L$. Moreover, we assume the discrete error $\|(\mathbb{E}[Q_L] - \mathbb{E}[Q])^2\| = O(h_L^\alpha)$ for some constant $\alpha > 0$.

**Total computational cost of MLMC:**

$$
T_c = N_0C_0 + \cdots + N_LC_L.
$$

**Computational accuracy of MLMC:**

$$
e_L = N_0^{-1}V_0 + \cdots + N_L^{-1}V_L + O(h_L^\alpha).
$$
Sample Size Formulae

Sample size formulae are derived from two optimization perspectives: minimizing the computational error/cost with given computational complexity/accuracy:

\[
\text{Opt 1 : } \left\{ \begin{array}{l}
\text{Minimize } e_L = N_0^{-1} \mathcal{V}_0 + N_1^{-1} \mathcal{V}_1 + \ldots + N_L^{-1} \mathcal{V}_L + \mathcal{O}(h_L^\alpha), \\
\text{subject to } T^*_c = N_0 C_0 + N_1 C_1 + \ldots + N_L C_L.
\end{array} \right. 
\]

(7)

By solving this integer optimization problem, we derive

\[ N_0 = \sqrt{\frac{\mathcal{V}_0}{C_0}} \frac{T^*_c}{\sqrt{C_0 \mathcal{V}_0 + \ldots + \sqrt{C_L \mathcal{V}_L}}} \quad \text{and} \quad N_i = N_j \sqrt{\frac{C_j}{C_i}} \cdot \frac{\mathcal{V}_i}{\mathcal{V}_j} \quad \text{for } 0 \leq i \neq j \leq L. \]

Opt 2 : \left\{ \begin{array}{l}
\text{Minimize } T_c = N_0 C_0 + N_1 C_1 + \ldots + N_L C_L, \\
\text{subject to } e_L^* - \mathcal{O}(h_L^\alpha) = N_0^{-1} \mathcal{V}_0 + N_1^{-1} \mathcal{V}_1 + \ldots + N_L^{-1} \mathcal{V}_L.
\end{array} \right. 
\]

(8)

Similarly, we derive

\[ N_0 = \sqrt{\frac{\mathcal{V}_0}{C_0}} \left( \frac{\sqrt{\mathcal{V}_0 C_0 + \ldots + \sqrt{\mathcal{V}_L C_L}}}{e_L^* - \mathcal{O}(h_L^\alpha)} \right) \quad \text{and} \quad N_i = N_j \sqrt{\frac{C_j}{C_i}} \cdot \frac{\mathcal{V}_i}{\mathcal{V}_j} \quad \text{for } 0 \leq i \neq j \leq L. \]

Concluding Remarks
MLMC Analyses

WLOG, let the sequence of triangulations $\{T_\ell\}_{\ell=0}^L$ satisfies the subdivision strategy which leads to $h_\ell = 2^{-1}h_{\ell-1}$ for $\ell = 1, \ldots, L$, suppose the following assumptions\(^\S\)

\[ A1. \quad \mathcal{V}_\ell = \begin{cases} 
\|\nabla [Q_0]\| = c_0, \\
\|\nabla [Q_\ell - Q_{\ell-1}]\| = \mathcal{O}(h_\ell^\beta) \quad \text{for} \quad \ell = 1, \ldots, L,
\end{cases} \]

\[ A2. \quad C_\ell = \mathcal{O}(h_\ell^{-\gamma}) \quad \text{for} \quad \ell = 0, \ldots, L. \]

hold for some positive constants $\beta$ and $\gamma$, then for $1 \leq i < j \leq L$,

\[ \frac{N_j}{N_i} = \sqrt{\frac{C_i}{C_j}} \cdot \frac{\mathcal{V}_j}{\mathcal{V}_i} = \left( \frac{h_j}{h_i} \right)^{\frac{\beta+\gamma}{2}} = 2^{-\left(\frac{(j-i)(\beta+\gamma)}{2}\right)} < 1, \quad (9) \]

which implies that the finer the mesh is, the fewer the realizations we need to compute.

Now note that, the sample size of initial level could be determined by $C_0$, $\mathcal{V}_0$ and $\mathcal{V}_1$ defined on coarse meshes by low cost, while the others could be derived via (9).

Concluding Remarks
2D Stochastic Optimal Control Problem

Given a deterministic target function $U(x) = \sin(2\pi x) (\cos(2\pi y) - 1)$ and $\beta = 10^{-4}$, find the optimal solution pair $(u^{\text{opt}}, f^{\text{opt}}) \in H^1_0(D) \otimes L^2(D)$ such that

$$\widehat{J}_\beta (u, f) = \frac{1}{2N} \sum_{i=1}^{N} \int_{D} |u(x, \omega_i) - U(x)|^2 dx + \frac{\beta}{2} \int_{D} |f(x)|^2 dx$$

subject to the stochastic elliptic PDEs

$$\begin{cases} 
-\nabla \cdot (a(x, \omega_i) \nabla u(x, \omega_i)) = f(x) & \text{in } D = [0, 1]^2 \\
u(x, \omega_i) = 0 & \text{on } \partial D
\end{cases}$$

for $i = 1, \ldots, N$,

is minimized, where the coefficient $a(x, \omega) = e^{g(x, \omega)}$ is given as before.

Using 4-level grids $\{h_\ell = 2^{-\ell-2}\}_{\ell=0}^3$, the MLMC approximation of $\mathbb{E}[u^{\text{opt}}]$ is given by

$$\mathbb{E} \left[ u_{3}^{\text{opt}} \right] = \frac{1}{N_0} \sum_{i=1}^{N_0} u_{0}^{\text{opt},(i)} + \sum_{\ell=1}^{3} \frac{1}{N_\ell} \sum_{i=1}^{N_\ell} (u_{\ell}^{\text{opt},(i)} - u_{\ell-1}^{\text{opt},(i)}).$$
In order to utilize the characteristics of GBR, we use the following 7 points quadrature rule of order 3 that defined on a reference triangle with vertices \((0, 0), (1, 0)\) and \((0, 1)\).

Nested quadrature points from nested finite element spaces.
Sensitive Analysis

Two key observations:

- the optimal solution $u^{\text{opt}}(x, \omega)$ of surrogate model problem (5-6) solves elliptic problem (1) with a particular right hand side $f^{\text{opt}}(x)$, while $u^{\text{ite}}(x, \omega)$ with $f^{\text{ite}}(x)$ during the iterations,

- it is cheaper/easier to determine the parameters $\alpha, \beta, \gamma$ numerically/theoretically for elliptic problem than the optimal control problem.

Inspiration: use the parameters of state constraint for the optimal control problem.

The parameters of state problem are numerically determined with various RHSs:

Smooth functions:
\[
 f(x) = \begin{cases} 
 \sin(x) \cos(y) & \text{in } D = [0, 1]^2, \\
 x^2 + y^2 & \text{in } D = [0, 1]^2, \\
 e^{x+y} & \text{in } D = [0, 1]^2.
\end{cases}
\]  

(10)

Non-smooth functions:
\[
 f(x) = \sigma \sum_{k=1}^{K} \frac{1}{\sqrt{V_k}} \chi_k(x) X_k(\omega) \text{ in } D = [0, 1]^2.
\]  

(11)

β almost doesn’t change w.r.t. smooth RHSs (10) when the same coefficient is provided.

</table>

**Observation:** the value of $\gamma$ roughly equals to the dimension of problem in our case.

**Conclusion:** given that $V[\beta]$ and $V[\gamma]$ are small, the values of $\beta$ and $\gamma$ would be very stable if $f(x)$ varies in a certain range for both smooth and non-smooth functions.

**Application:** in surrogate model problem (5-6), the RHSs of both state and adjoint equations vary along with the iterations. Then by our conclusion, the parameters $\beta$ and $\gamma$ of our surrogate model problem are stable when the same coefficient is provided and can be numerically obtained via sensitive analysis.

Stochastic Optimal Control Problem

• Stochastic elliptic problem
• Stochastic optimal control problem

Multilevel Monte Carlo Method

• Introduction to multilevel Monte Carlo method
• Analysis to multilevel Monte Carlo method

Numerical Experiment

• 2D stochastic optimal control problem

Concluding Remarks
Concluding Remarks

- MLMC inherits the advantage of Monte Carlo method as being insensitive to the dimension of probability space.

- MLMC performs most simulations with low accuracy at a low cost, with relatively few simulations being performed at high accuracy and a high cost.

- By applying a grid-based representation to the stochastic coefficient, the dimensionality of random fields in our MLMC scheme is also a multilevel type, which further reduces the computational cost and avoids the truncation error in KLE.

- The stability of parameters is verified via sensitivity test, which indicates the applicability of the MLMC formulas for our stochastic optimal control problem.

- The idea using the parameters of state constraint for the optimization problem is shown to be an economical and reliable approach. This can be a contribution that is potentially applicable to other optimal control problems with different objective functionals and state equations.

- Theoretical verification of MLMC assumption, preconditioned conjugate gradient method and optimal choices of parameters will be carried out in the future.
Thank you
