In this paper, the continuous adjoint method to compute shape sensitivities in aerodynamic design with turbulence modeling is described and developed. The focus is on compressible flows described by the Reynolds-averaged Navier–Stokes equations and the classical Spalart–Allmaras model for turbulence. Turbulence modeling usually requires, in particular, computation of the distance to the surface. Here, this distance is incorporated to the system as a new variable, solving the Eikonal equation. The accuracy of the sensitivity derivatives obtained with the complete turbulent approach is assessed by comparison with finite difference computations and the classical continuous adjoint with frozen viscosity, showing substantial improvements in the convergence properties of the method and in the quality of the obtained gradients. The validity of the overall methodology is illustrated with several design examples, including the optimization of three-dimensional geometries in combination with advanced freeform techniques for mesh deformation.

I. Introduction

This paper contains a complete formulation of the continuous adjoint approach for the shape optimization of an obstacle with a boundary $S$ immersed in a fluid governed by the Reynolds-averaged Navier–Stokes (RANS) equations. We focus on the Spalart–Allmaras turbulence model [1], due to its wide use in aerodynamic industry. As a result, a system of partial differential equations (PDEs), suitable for numerical simulation at a relatively low cost but still retaining significant properties of the turbulent flow, is obtained.

Shape optimization methods have grown in importance in aerodynamic design within the last decade. In gradient-based optimization techniques, the goal is to minimize a suitable cost or objective function (drag coefficient, deviation from a prescribed surface pressure distribution, etc.) with respect to a set of design variables (defining, for example, an airfoil profile or aircraft surface). Minimization is achieved by means of an iterative process that requires the computation of the gradient or sensitivity derivative of the cost function with respect to the design variables.

Gradients can be computed in a variety of ways, the most actively pursued one being the adjoint method [2–5] due, among other factors, to its ability of computing these derivatives at a cost comparable with that of numerically solving the state PDEs. Adjoint methods are conventionally subdivided into continuous and discrete methods. In the continuous approach, the adjoint equations are derived from the governing PDEs and subsequently discretized to obtain a descent direction for the discrete cost functional, whereas in the discrete approach, this descent direction is directly obtained from the adjoint equations that discretized PDEs [6].

In the continuous adjoint approach, the adjoint system is a linear system of PDEs that can be discretized using any convergent numerical scheme. One can take advantage of this, but it requires a suitable numerical analysis of the underlying system of equations. Note that the adjoint equations are not derived directly from a physical model, and their numerical analysis is not similar to the one required for the fluid equations. In particular, stability and convergence must be analyzed independently. It is worth mentioning that this is not an easy problem when singularities appear. For instance, consistency of adjoint problems in the presence of shock waves is a difficult topic [7–10]. Moreover, mathematical and physical understanding of the adjoint problem is aided by considering the continuous approach, as exemplified by analytic adjoint solutions for one-dimensional Euler problems [11].

On the contrary, the discrete adjoint provides the exact gradient of the discretized objective function (as the finite differences method or the complex step method [12]). The discrete adjoint is also often considerably harder than the continuous one in terms of operation counts and memory requirements, although some efficient codes have been developed to mitigate these limitations [13–15]. Besides, the discrete adjoint becomes complex for higher-order schemes (see [6] and references therein), and it is not always well justified since it requires the linearization of the underlying numerical scheme used to approximate the flow system. Any efficient second-order numerical scheme able to approximate the conservative part of the fluid system in the presence of singular solutions is nondifferentiable in nature. Thus, any approximation of the linearized discrete system should be carefully analyzed from the mathematical point of view. Finally, related with the discrete adjoint, it is interesting to highlight the concept of dual consistency [16], which leads to a discrete adjoint problem that is a consistent discretization of the continuous adjoint problem that we are going to derive in this paper.

II. Description of the Problem

The Navier–Stokes equations [26,27] (see Appendix A) describe the conservation of mass, momentum, and energy in a viscous fluid. Classical aeronautical applications assume that the air is governed by these Navier–Stokes equations on a domain $\Omega \subset \mathbb{R}^3$ delimited by disconnected boundaries divided into a far field $\Gamma_\infty$ and adiabatic walls that we denote by $S$. Their steady-state formulation (without source terms) can be written in the following form:

$$\begin{align*}
R(U, t) &= \nabla \cdot F_U - \nabla \cdot \left( \mu_{tot} F_{\nabla U} + \mu_{comp} \nabla^2 U \right) = 0 \quad \text{in} \quad \Omega \\
\mathbf{v} &= 0 \quad \text{on} \quad S \\
\partial_n F_{\nabla U} &= 0 \quad \text{on} \quad S \\
\left( W_{\kappa} - W_{\infty} \right) \cdot n &= 0 \quad \text{on} \quad \Gamma_\infty
\end{align*}$$

where $U = (\rho, \rho v_1, \rho v_2, \rho v_3, \rho E)^T$ stands for the vector of conservative variables, $\rho$ is the density, $E$ is the energy, $\mathbf{v} = (v_1, v_2, v_3) \in \mathbb{R}^3$ is the flow speed in a Cartesian system of reference,
and \( T \) is the temperature. The last equation in Eq. (1) represents classical far-field boundary conditions simulating the fluid behavior at infinity. The vectors \( \mathbf{F}^k (U) = (F_{1k}, F_{2k}, \ldots, F_{nk}) \) are the convective fluxes and \( \mathbf{F}^{k\alpha} (U) = (F_{1k\alpha}, F_{2k\alpha}, \ldots, F_{nk\alpha}) \), \( k = 1, 2 \), are the viscous fluxes, where we have considered separately the contribution of the viscous forces and the heat flux transfer. Here, \( (\cdot)^T \) denotes transposition.

As usual in turbulence modeling based upon the Boussinesq hypothesis, which states that the effect of turbulence can be represented as an increased viscosity, the viscosity is divided into laminar \( \mu_{\text{dyn}} \) and turbulent \( \mu_{\text{tur}} \) components. The laminar or dynamic viscosity is usually taken to be only dependent on the temperature \( \mu_{\text{dyn}} = \mu_{\text{dy}}(T) \), whereas \( \mu_{\text{tur}} \) is obtained from a suitable turbulence model involving the flow and a set of new variables \( \tilde{v} \), i.e., \( \mu_{\text{tur}} = \mu_{\text{tur}}(U, \tilde{v}) \). Here, we assume that \( \tilde{v} \) is a single scalar variable obtained from a one-equation turbulence model, which in general form can be written as

\[
\begin{align*}
R_1(U, \tilde{v}, d_s) &= \nabla \cdot \mathbf{T}^v - T^v = 0 \quad \text{in } \Omega \\
\hat{v} &= 0 \quad \text{on } S \\
\hat{v}_\infty &= \sigma_\infty v_\infty \quad \text{on } \Gamma_\infty
\end{align*}
\]

where \( \mathbf{T}^v = \mathbf{T}^v(U, \tilde{v}, d_s) \) stands for the convective and viscous terms, \( T^v = T^v(U, \tilde{v}, d_s) \) represents the source term, and \( d_s \) is the distance to the boundary of the obstacle \( \Omega \). In the particular case of the Spalart–Allmaras model, the convective, viscous, and source terms are given in Appendix B. The far-field boundary condition for the turbulent viscosity in Eq. (2) imposes some fraction of the laminar viscosity at the far field. This is usual in turbulence modeling [1], where \( \sigma_\infty \) is a turbulence model constant, usually ranging between 3 and 5. On viscous walls, \( \hat{v} \) is set to zero, corresponding to the absence of turbulent eddies very near to the wall.

Turbulence and mainstream flow then become coupled by replacing the dynamic viscosity in the momentum and energy equations in the Navier–Stokes equations with

\[
\mu^1_{\text{tot}} = \mu_{\text{dy}} + \mu_{\text{tur}}, \quad \mu^2_{\text{tot}} = \frac{\mu_{\text{dy}}}{\Pr_d} + \frac{\mu_{\text{tur}}}{\Pr_t}
\]

where \( \Pr_d \) and \( \Pr_t \) are, respectively, the dynamic and turbulent Prandtl numbers. Here, \( \mu_{\text{tur}} \) represents the effective thermal conductivity that we write in this nonstandard notation to obtain reduced expressions in the calculus below.

Note that, in Eq. (2), we have incorporated the distance variable \( d_s \), which is common in turbulence modeling and, in particular, it appears in the considered Spalart–Allmaras model. The new variable \( d_s(\Omega) \) is defined as the so-called Eikonal equation:

\[
\begin{align*}
R_d(d_s) &= |\nabla d_s|^2 - 1 = 0 \quad \text{in } \Omega \\
d_s &= 0 \quad \text{on } S
\end{align*}
\]

Systems (1), (2), and (4), together with a suitable equation of state to describe the fluid thermodynamics, constitute a complete system of equations and boundary conditions for the flow variables [28, 29].

A key element for the definition of an optimal shape design problem is the objective function. In this case, we introduce an objective function that is assumed to be only dependent on the values of the flow variables at the boundary \( S \). As shown in [5], for the Navier–Stokes system, only objective functions depending on \( \mathbf{f} \) and the temperature \( T \) are allowed for continuous adjoint optimization, with \( \mathbf{f} \) given by

\[
\mathbf{f} = (f_1, f_2, f_3) = \mathbf{P} \mathbf{n} - \bar{\sigma} \cdot \mathbf{n}, \quad \bar{\sigma} = \mu^1_{\text{tot}} \bar{\tau}
\]

where \( \mathbf{n} \) denotes the exterior normal to the surface \( S \), \( \mathbf{P} \) is the pressure of the fluid, and \( \bar{\sigma} \) is the second-order tensor of viscous stresses, with \( \bar{\tau} \) given in Appendix A. Note that this includes, in particular, functionals depending only on the pressure \( \mathbf{P} \), since it can be written as a function of \( \mathbf{f} \), using the fact that \( \mathbf{n} \cdot \bar{\sigma} \cdot \mathbf{n} = 0 \) on the boundary [5].

More precisely,

\[
P = \mathbf{n} \cdot (P + \bar{\sigma} \cdot \mathbf{n}) = \mathbf{f} \cdot \mathbf{n} \quad \text{on } S
\]

In the presence of turbulence modeling, a similar situation applies, the only difference being that we can now add a dependence on the unknown turbulence variable \( \bar{\sigma} \) on \( S \). Thus, for the purposes of the present study, we will consider the following general choice of objective function:

\[
J(S) = \int_S j(\mathbf{f}, T, \bar{\sigma} \cdot \mathbf{n}) \, ds
\]

III. Variation of the Objective Function: The Adjoint Approach

As usual in the adjoint approach, flow equations are incorporated to the cost functional as constraints by means of a Lagrange multiplier for each equation, \( \Psi^1_i = (\psi_1, \psi_2, \psi_3, \psi_4, \psi_5, \psi_6) \). In this way, the Lagrangian reads

\[
J(S) = \int_S j(\mathbf{f}, T, \bar{\sigma} \cdot \mathbf{n}) \, ds + \int_S (\Psi^1_i R_{\psi_i}(U, \tilde{v})

\psi_i R_{\psi_i}(U, \tilde{v}, d_s) + \psi_d R_{\psi_d}(d_s)) \, d\Omega
\]

Let us consider an arbitrary (but small) perturbation of the boundary \( S \) that, without loss of generality, can be parameterized by an infinitesimal deformation of size \( \delta S \) along the normal direction to the surface \( S \). The new surface obtained after the deformation is then given by

\[
S' = \{ \mathbf{x} + \delta \mathbf{n} \mathbf{x} \in S \}
\]

where for small deformations, the following holds [30]:

\[
\delta f = -\nabla_s (\delta S) \quad \delta (ds) = -2H_n \delta S ds
\]

where \( H_n \) is the mean curvature of \( S \) computed as \((k_1 + k_2)/2\), and \( \{ \kappa_1, \kappa_2 \} \) are curvatures in two orthogonal directions on the surface. Here, \( \nabla_s \) represents the tangential gradient operator on \( S \). Note that \( \nabla_s (\delta S) \) is a tangent vector to \( S \) that we write as a vector in \( \mathbb{R}^3 \) with a null component normal to \( S \).

Assuming a regular flow solution \( U \) and a smooth boundary \( S \), the variation of the functional \( J \) due to the deformation can be evaluated as

\[
\delta J = \int_S \delta j(\mathbf{f}, T, \bar{\sigma} \cdot \mathbf{n}) \, ds + \int_S j(\mathbf{f}, T, \bar{\sigma} \cdot \mathbf{n}) \, ds

+ \int_S (\Psi^1_i \delta R_{\psi_i}(U, \tilde{v}) + \psi_i \delta R_{\psi_i}(U, \tilde{v}, d_s) + \psi_d \delta R_{\psi_d}(d_s)) \, d\Omega
\]

where \( \delta R_{\psi_i}, \delta R_{\psi_d}, \) and \( \delta R_{\psi_d} \) represent the variations of \( R_{\psi_i}, R_{\psi_d}, \) and \( R_{\psi_d} \), respectively. Using the convention of summation of repeated indexes, \( i = 1, 2, 3 \), the two first terms in the previous equation read

\[
\delta j(\mathbf{f}, T, \bar{\sigma} \cdot \mathbf{n}) = \frac{\partial j}{\partial f_i} \delta f_i + \frac{\partial j}{\partial T} \delta T + \frac{\partial j}{\partial (\bar{\sigma} \cdot \mathbf{n})} \delta (\bar{\sigma} \cdot \mathbf{n}) - \frac{\partial j}{\partial \mathbf{n}} \cdot \nabla_s (\delta S)
\]

\[
= \frac{\partial j}{\partial \mathbf{n}} \cdot (\delta P \mathbf{n} - \bar{\sigma} \cdot \mathbf{n}) + \frac{\partial j}{\partial T} \delta T + \frac{\partial j}{\partial (\bar{\sigma} \cdot \mathbf{n})} \delta (\bar{\sigma} \cdot \mathbf{n})

- \left( \frac{\partial j}{\partial \mathbf{n}} + \frac{\partial j}{\partial T} \mathbf{P} + \frac{\partial j}{\partial T} \bar{\sigma} \right) \cdot \nabla_s (\delta S)
\]

\[
= \int_S \left( \frac{\partial j}{\partial f_i} \delta f_i + \frac{\partial j}{\partial T} \delta T + \frac{\partial j}{\partial (\bar{\sigma} \cdot \mathbf{n})} \delta (\bar{\sigma} \cdot \mathbf{n}) - \frac{\partial j}{\partial \mathbf{n}} \cdot \nabla_s (\delta S)

+ \frac{\partial j}{\partial (\bar{\sigma} \cdot \mathbf{n})} \delta (\bar{\sigma} \cdot \mathbf{n}) - 2H_n f \right) \, ds
\]
Note that, in Eq. (12), we have written the variation $\delta f$ in terms of $\delta P$ and $\delta \delta$, and we have used formula (10) for $\delta n$. The variations $\delta P \mathbf{n} - \delta \delta \cdot \mathbf{n}$, $\delta T$, and $\delta (\delta \mathbf{v})$ appearing in Eq. (12) can be computed from the following linearized system:

$$\left\{ \begin{array}{l}
\delta R_c(U, \mathbf{v}, \delta S) = \frac{\partial R_c}{\partial U} \delta U + \frac{\partial R_c}{\partial \mathbf{v}} \delta \mathbf{v} = 0 \quad \text{in } \Omega \\
\delta \mathbf{v} = -\partial_1 \mathbf{v} \delta S \quad \text{on } S \\
\partial_2 (\delta T) = (VT) \cdot \nabla_s (\delta S) - \partial_2^T T \delta S \quad \text{on } S \\
(\delta W)_c = 0 \quad \text{on } \Gamma_\infty
\end{array} \right. \quad (14)$$

$$\left\{ \begin{array}{l}
\delta \mathbf{v} = -\partial_1 \mathbf{v} \delta S \quad \text{in } \Omega \\
\delta \mathbf{v} = \sigma_\infty \delta \mathbf{v} \quad \text{on } \Gamma_\infty
\end{array} \right. \quad (15)$$

$$\left\{ \begin{array}{l}
\delta R_d(s) = \nabla d_s \cdot \nabla \delta d_s = 0 \quad \text{in } \Omega \\
\delta d_s = \delta S \quad \text{on } S
\end{array} \right. \quad (16)$$

where $(\delta W)_c$ represents the incoming characteristics on the far-field boundary. Linearization of the Navier–Stokes and the Spallart–Allmaras equations are, respectively, given in Appendices C and D.

In the last formula of Eq. (16), we have used the fact that $\partial_1 d_s = -1$; therefore, $\delta d_s = -\partial_1 \mathbf{d} \delta S = \delta S$.

Domain integrals in Eq. (11) are eliminated using integration by parts and introducing the associated adjoint operators. This integration by parts also provides some boundary terms, which are combined with the boundary terms in Eq. (11) depending on $\delta P \mathbf{n} - \delta \delta \cdot \mathbf{n}$, $\delta T$, and $\delta (\delta \mathbf{v})$, yielding the boundary conditions for the adjoint operators. We describe this process below.

From Eqs. (14–16), the last three terms in Eq. (11) read

$$\int_\Omega \Psi_U \left( \frac{\partial R_c}{\partial U} \delta U + \frac{\partial R_c}{\partial \mathbf{v}} \delta \mathbf{v} \right) + \int_\Omega \Psi_\mathbf{v} \left( \frac{\partial R_c}{\partial U} \delta U + \frac{\partial R_c}{\partial \mathbf{v}} \delta \mathbf{v} + \frac{\partial R_c}{\partial d_s} \delta d_s \right) + \int_\Omega \delta \mathbf{v} \frac{\partial R_c}{\partial d_s} = \int_\Omega (A_U \Psi_U + A_\mathbf{v} \Psi_\mathbf{v}) \delta U + \int_\Omega (A_U \Psi_U + A_\mathbf{v} \Psi_\mathbf{v}) \delta \mathbf{v} + \int_\Omega (A_\mathbf{v} \Psi_U + A_U \Psi_\mathbf{v}) \delta d_s + \int_\Omega B_s \delta d_s \quad (17)$$

where $A_U = (\partial R_c/\partial U)^T$, $A_\mathbf{v} = (\partial R_c/\partial \mathbf{v})^T$, $A_\mathbf{v} = (\partial R_c/\partial U)^T$, $A_U = (\partial R_c/\partial \mathbf{v})^T$, $A_\mathbf{v} = (\partial R_c/\partial d_s)$, and $A_U = (\partial R_c/\partial d_s)$ are the adjoint operators and $B_s$ stands for the boundary terms coming from the integration by parts

$$\int_S B_s \delta d_s = - \int_S \Psi \cdot (\delta P \mathbf{n} - \delta \delta \cdot \mathbf{n}) \delta d_s - \int_S \left( g_1 \cdot \mathbf{v} + g_2 \partial_1 \mathbf{v} + \psi_\delta \partial_1 \mathbf{v} \right) ds - \int_S g_3 \psi_\delta \delta d_s \delta d_s + \int_S \delta \mathbf{v} \cdot \nabla S ds \quad (18)$$

where $\Psi = (\psi_1, \psi_2, \psi_3, \psi_4, \psi_5)$ and $g_i$, $g_i$, $i = 2, 3, 4, 5$, are some functions that do not depend on the adjoint variables $\Psi_U, \psi_\delta, \psi_i, \psi_i$, and $\mathbf{g}$, which does not depend on $\psi\delta$. The analytical expression of these terms and the adjoint operators above are given in detail in Eqs. (E4–E13) in Appendix E.

We now observe that, due to the relation Eq. (6), the first and third terms on the right-hand side of Eq. (18) can be written together. In fact, the linearization of Eq. (2) provides:

$$\delta P = (\delta P \mathbf{n} - \delta \delta \cdot \mathbf{n}) = \mathbf{n} \cdot (\delta P \mathbf{n} - \delta \delta \cdot \mathbf{n}) - 2(\delta P \mathbf{n} - \delta \delta \cdot \mathbf{n}) \cdot \nabla_S (\delta S) \quad (19)$$

where we have used the symmetry of the tensor $\delta$ and the formula for $\delta n$ in Eq. (10). Therefore, Eq. (18) can be written as

$$\int_S B_s \delta d_s = \int_S \left( -\varphi + \psi_\delta g_1 \mathbf{n} \right) \cdot (\delta P \mathbf{n} - \delta \delta \cdot \mathbf{n}) ds - \int_S \left( g_1 \cdot \varphi + g_2 \partial_1 \varphi + \psi_\delta \psi_3 \right) \delta T ds - \int_S g_3 \psi_\delta \delta (\delta \mathbf{v}) ds - \int_S \psi_\delta g_4 (P \mathbf{n} - \delta \delta \cdot \mathbf{n}) \cdot \nabla_S (\delta S) ds \quad (20)$$

To eliminate domain integrals in Eq. (11) when replacing the last three terms by using Eq. (17), we assume that the adjoint variables satisfy

$$0 = A_U \Psi_U + A_\mathbf{v} \Psi_\mathbf{v} \quad (21)$$

$$0 = A_U \Psi_U + A_\mathbf{v} \Psi_\mathbf{v} \quad (22)$$

$$0 = A_U \Psi_U + A_\mathbf{v} \Psi_\mathbf{v} \quad (23)$$

Analogously, all boundary terms in Eq. (17) without explicit dependence on $\delta S$ can be eliminated by considering the following choice of boundary conditions for the adjoint variables:

$$\psi_\delta = \frac{1}{g_2} \frac{\partial j}{\partial \mathbf{n}} \quad (24)$$

$$\psi_i = \frac{\partial j}{\partial \mathbf{n}} + \psi_\delta g_4 n_i \quad (25)$$

$$\partial_2 \psi_\delta = \frac{1}{g_2} \left( g_1 \cdot \varphi + \psi_\delta \psi_3 \right) \quad \text{on } S \quad (26)$$

$$\psi_d = 0 \quad \text{on } S \quad (27)$$

Note that this choice for the boundary conditions must be done in an ordered manner; that is, the value of $\psi_\delta$ on the right-hand sides of Eqs. (25) and (26) is obtained from Eq. (24), whereas the value of $\varphi$ in Eq. (26) is computed from Eq. (25).

Combining Eqs. (11–13) and (17–20), adjoint equations (21–23), and the boundary conditions in Eqs. (24–27), we finally obtain

$$\delta \mathcal{F} = \int_S \frac{\partial j}{\partial \mathbf{n}} \partial_1 \mathbf{v} + \frac{\partial j}{\partial \mathbf{n}} \partial_2 \mathbf{v} + \frac{\partial j}{\partial \mathbf{n}} \partial_3 \mathbf{v} \cdot \nabla_S (\delta S) ds - \int_S \left( \frac{\partial j}{\partial \mathbf{n}} + \frac{\partial j}{\partial \mathbf{n}} P - \frac{\partial j}{\partial \mathbf{n}} \right) \cdot \nabla_S (\delta S) ds - \int_S (\varphi + 2 H_m) \delta S ds - 2 \int_S \psi_\delta g_4 (P \mathbf{n} - \delta \delta \cdot \mathbf{n}) \cdot \nabla_S (\delta S) ds \quad (28)$$

In this expression, the adjoint variables are obtained by solving the closed system of PDEs and boundary conditions given by Eqs. (21–27).

It is important to recall here that neither the Navier–Stokes adjoint equation in Eq. (21) nor the Spallart–Allmaras adjoint equation in Eq. (22) depends on the adjoint distance variable $\psi_\delta$. This is also the case of the functional sensibility equation (28), since typical objective functionals in aerodynamics do not depend explicitly on the distance to the surface. In this situation, it is therefore not necessary to solve Eq. (23), and the adjoint system simply reduces to Eqs. (21) and (22). One could consider, however, more sophisticated situations that would require the solution of Eq. (23). This could be,
for instance, the case of functionals with an explicit dependence on the distance to the surface by means of a domain integral. Some particular but still interesting situations provide a more simplified formula for the variation of $J$, as described in [5] for the Navier–Stokes equations. Assume that the objective function depends only on $f$ in the following way:

$$j(f) = f \cdot d$$

(29)

where $d$ is a constant vector (the choice $d = n$ is also possible with some modifications, but for simplicity, we focus on constant $d$). Note that this is the case in drag or lift optimization problems. The adjoint boundary conditions in this situation simply become

$$\psi_b = \psi_d = 0, \quad \phi = d, \quad \partial_n \psi_s = g \cdot d / g_2$$

(30)

and the variation of $J$ is given by

$$\delta J = \int_S d \cdot \partial_n f \cdot \delta S \, ds - \int_S (Pd - d \cdot \hat{\sigma}) \cdot \nabla_s (\delta S) \, ds$$

$$- \int_S (\hat{\psi} + 2H_m) \delta S \, ds$$

(31)

Integrating now by parts, and assuming that either $S$ is smooth or $\delta S = 0$ at its singular points, yields

$$\delta J = \int_S \partial_n (Pd - d \cdot \hat{\sigma}) \cdot \delta S \, ds + \int_S \nabla \cdot (Pd - d \cdot \hat{\sigma}) \delta S \, ds$$

$$- \int_S \hat{\psi} \delta S \, ds = - \int_S \hat{\psi} \delta S \, ds$$

(32)

Here, we have used the fact that the divergence operator, on local coordinates of $S$, is given by

$$\nabla \cdot q = \partial_n (q \cdot n) + \nabla \cdot q - 2H_m q \cdot n$$

(33)

for a general vector field $q$, and the identity

$$\nabla \cdot (Pd - d \cdot \hat{\sigma}) = (\nabla P - \nabla \cdot \hat{\sigma}) \cdot d = 0 \quad \text{on} \quad S$$

(34)

which is obtained assuming that the momentum equations in the Navier–Stokes system are satisfied on the boundary, i.e., $\nabla P = \nabla \cdot \hat{\sigma}$ on $S$.

The final expression in Eq. (32) involves the function $\hat{\psi}$ that, as shown in Appendix E, is reduced to $\hat{\psi} = h$, given by Eq. (E.12), due to the boundary conditions in Eq. (30). In this way, the expression for the total variation of the adjoint field to be used will be simplified as follows:

$$\delta J = - \int_S \hat{\psi} \delta S \, ds = \int_S (n \cdot \Sigma_p \cdot \partial_n \nu - \mu_{\alpha} C_p \nabla \psi \cdot \nabla s(T) \delta S \, ds$$

(35)

with $\Sigma_p$ depending on the gradient of the adjoint variables $\phi$. Note that we are supposing a smooth flow solution; a complete Euler adjoint formulation with shock waves can be found in [31].

IV. Numerical Implementation of the Shape Optimization Framework

An appropriate rearrangement of terms in the vector-matrix multiplications in Eqs. (21) and (22) leads to a more suitable formulation for the numerical evaluation of the residuals of the adjoint system. Compact expressions for the evaluation of these terms, as well as a description of the other components of the whole shape optimization framework, are presented in this section.

A. Spatial Discretization

A finite volume discretization is used to solve both the direct and adjoint equations. As usual, the finite volume discretization is obtained by applying the integral formulation of the governing equations to a control volume $\Omega_h$, consisting of a cell of the dual mesh surrounding each node.

To avoid any possible confusion, the standard Latin indexes $i, j$ will be reserved here to indicate spatial coordinates. For those residuals computed as the addition of several fluxes through the faces of a dual mesh cell, the central node of the cell will be denoted with the local index 0, and its set of neighboring points labeled as $N_0 = \{1, \ldots, N_0\}$, with $N_0$ representing the size of the set.

1. Reynolds-Averaged Navier–Stokes Equations

The solution of flow equation (1) and turbulence model equation (2) enter on the adjoint equations as the coefficients of the adjoint system. For the flow equations, a central scheme with a Jameson–Schmidt–Turkel (JST)-type scalar artificial dissipation [32,33] is used for the discretization of the convective flux. The convection of the turbulent variable $\hat{v}$ is discretized using a fully upwind scheme. Second-order accuracy is easily achieved via reconstruction of variables on the cell interfaces using a MUSCL approach with limitation of gradients [34]. In both cases, viscous fluxes are computed with the node-gradient-based approach due to Weiss et al. [35] that, apart from reducing the truncation error of the scheme, avoids the odd–even decoupling of mesh nodes in the computation of residuals, resulting in second-order spatial accuracy. Source terms are approximated via piecewise reconstruction in the finite volume cells.

The solution of turbulence model equation (2) also requires the numerical approximation of the Eikonal equation (1), in order to compute the distance field to the boundary of the obstacle. Our implementation makes use of an efficient fast-marching solver for unstructured grids [36] based on a finite element approximation to the Eikonal equation in each mesh element. Second-order accuracy is recovered by using not only the information of the nodal values of the distance field but incorporating the direction of the computed $\nabla d_s$ into the solver [37].

2. Adjoint Flow Equation

a. Convective Residuals. A modified version of the JST scheme without low-order-dissipation is used for the discretization of the convective term [5]. This is given by

$$R_{U, \text{conv}} = \int_{\Omega_h} \nabla \hat{\psi} : A^* \text{d} \Omega \approx \sum_{h \in \Omega_h} R_{U, \text{conv}}$$

(36)

with $A^*$ defined in Eq. (6), which unfortunately is not written in conservative form, thus avoiding the direct application of the Green–Gauss theorem. However, this flux can be seen as a convection with nonconstant coefficients, given by the evaluation of matrices $A^*$ at the different mesh nodes. Hence, across the face of the control volume separating two mesh nodes with local indexes 0 and $n$, the component of the convective residual for node 0 can be computed as

$$R_{U, \text{conv}} = \frac{(v \cdot S) \psi_1 + \frac{\nu}{2} (v' - 1) I_{1\phi} - (v \cdot S) I_{2\phi}}{(v \cdot S) I_{3\phi} = -v_2 (y - 1) I_{1\phi} + S I_{2\phi}} + D_{\text{conv}}$$

(37)

where the adjoint variables are reconstructed at the cell face as $\hat{\psi}_1 = \frac{1}{2} (\Psi |_{0} + \Psi |_{1})$, whereas flow variables are evaluated at node 0 (equivalently for node $n$). In Eq. (37), $S = \Sigma_5 = (S_x, S_y, S_z)$ denotes the normal vector of the face located at the edge going from node 0 to node $n$ such that its length coincides with the face area, and we have introduced the following notation:

$$I_{1\psi} = (\phi \cdot S) + (v \cdot S) \psi_5$$

(38)
The artificial dissipation between two nodes, 0 and 1 for example, can be expressed as
\[
\mathcal{D}_{01} = \kappa^{(a)} \kappa^{(a)} (\nabla^2 \Psi_{\ell}|_0 - \nabla^2 \Psi_{\ell}|_1) \omega_{01} \lambda_{01}
\]
(40)
where the following abbreviations have been used:
\[
\Sigma_{ij} = \Sigma_{ij}^v + \Sigma_{ij}^s
\]
(48)
\[
\Sigma_{ij}^v = \mu_{\text{eff}} (\partial_i \varphi_j + \partial_j \varphi_i - \frac{2}{3} \delta_{ij} \nabla \cdot \varphi)
\]
(49)
\[
\Sigma_{ij}^s = \gamma \mu_{\text{eff}} \partial_i \psi_s
\]
(51)
\[
\Sigma^s = \gamma \mu_{\text{eff}} \nabla \psi_s \cdot \mathbf{S}
\]
(52)
For coherence with the discretization of the convective residuals, the gradients of the adjoint variables are averaged (making use of the Weiss correction) at the cell face, whereas flow variables are evaluated at node 0.

\textit{c. Source Terms Residuals.} The remaining terms in Eq. (E4) are treated as source terms and approximated via piecewise reconstruction of the solution in each finite volume cell. After some manipulations, the residual vector can be written as

\[
\mathcal{R}_{U_{\text{source}}} \approx |\Omega_a|
\]

\[
\begin{pmatrix}
-\frac{1}{2} \sigma_{ij} \partial_j \psi_s - \sum_{ij} \partial_j \left( \frac{u_i}{p} \right) + \left( \frac{2}{3} \alpha_j - \beta_j \right) \partial_i \psi_s + \frac{1}{p} \sum_{ij} \sigma_{ij} \partial_j v_i + \theta (|\mathbf{v}|^2 - E) + \xi \\
\frac{1}{2} \sigma_{1j} \partial_j \psi_s + \sum_{ij} \partial_j \left( \frac{1}{p} \right) - v_i \alpha_j \partial_j \psi_s - \frac{1}{p} \sum_{ij} \sigma_{ij} \partial_j v_i - \theta v_i \\
\frac{1}{2} \sigma_{2j} \partial_j \psi_s + \sum_{ij} \partial_j \left( \frac{1}{p} \right) - v_2 \alpha_j \partial_j \psi_s - \frac{1}{p} \sum_{ij} \sigma_{ij} \partial_j v_i - \theta v_2 \\
\frac{1}{2} \sigma_{3j} \partial_j \psi_s + \sum_{ij} \partial_j \left( \frac{1}{p} \right) - v_3 \alpha_j \partial_j \psi_s - \frac{1}{p} \sum_{ij} \sigma_{ij} \partial_j v_i - \theta v_3 \\
\alpha \partial_j \psi_s + \theta
\end{pmatrix}
\]
(53)

\[
\begin{align*}
\nabla^2 \Psi_{\ell}|_0 &= \sum_{n \in N} (\Psi_{\ell}|_n - \Psi_{\ell}|_0)
\end{align*}
\]
denotes the undivided Laplacian operator, \( N_i \) represents the size of the set of neighboring points to node 1, \( \psi_{0i} = \frac{1}{2} (\psi|_0 + \psi|_i) \) and \( c_0 = \frac{1}{2} (c_{10} + c_{11}) \) are the fluid and sound speeds at the cell face, and \( \kappa^{(a)} \) is an adjustable parameter. An artificial dissipation of upwind type could have been used as well, for which we refer the reader to [5].

\textit{b. Viscous Residuals.} The viscous residuals of the adjoint flow equation are discretized using the Green–Gauss integral relation:
\[
\begin{align*}
\mathcal{R}_{U_{\text{visc}}} &= \int_{\Omega_a} \nabla (\nabla^T \mu_{\text{eff}} \mathbf{D}^v) \cdot \mathbf{d} \Omega \\
&= \int_{\Omega_a} \nabla \Psi_{\ell}^T \cdot \mu_{\text{eff}} \mathbf{D}^v \cdot \mathbf{d} \mathbf{S} \approx \sum_{n \in N_0} \mathcal{R}_{U_{\text{visc}}}^{n}
\end{align*}
\]
(46)
with \( \mathbf{D}^v \) defined in Eq. (C6), which yields the following form for the viscous flux:
\[
\begin{pmatrix}
-v_1 \Sigma_j \sigma_j + \left( \frac{u_i}{p} - \frac{p}{17 p} \right) \Sigma^s \\
\Sigma_j \sigma_j - v_1 \Sigma^s \\
\Sigma_j \sigma_j - v_2 \Sigma^s \\
\Sigma_j \sigma_j - v_3 \Sigma^s
\end{pmatrix}
\]
(47)

\[
\begin{align*}
\alpha_i &= \gamma \mu_{\text{eff}} \partial_i \left( \frac{1}{p} \right) \\
\beta_i &= \frac{\gamma}{\gamma - 1} \mu_{\text{eff}} \partial_i \left( \frac{P}{\rho} \right) \\
\kappa_{\psi} &= \tau \nabla \varphi + \mathbf{v} \cdot \nabla \psi_s + \frac{C_p}{P_{fr}} \nabla T \cdot \nabla \psi_s
\end{align*}
\]
(54)

\[
\theta = \left[ \kappa_{\psi} \left( 1 - \frac{\mu_{\text{eff}}}{\mu_{\text{dyn}} \chi^2 + c_{11}} \right) - \frac{C_p}{P_{fr}} \nabla T \cdot \nabla \psi_s \left( 1 - \frac{Pr_{fr}}{Pr_d} \right) (\gamma - 1) \frac{\partial \mu_{\text{dyn}}}{\partial T} \right]
\]
(55)

\[
\xi = \kappa_{\psi} \left( 1 + \frac{c_{11}^3}{\chi^2 + c_{11}} \right) \frac{\mu_{\text{eff}}}{\rho}
\]
(58)

and \( \tau \nabla \varphi = \tau_i \partial_i \psi_s \), with \( \partial \mu_{\text{dyn}} / \partial T \) given by Eq. (C3). The two first terms are integrated using piecewise (p.w.) reconstruction, yielding a combined residual.
Finally, residuals coming from the:

\[ \mathbf{R}^{\text{source}}_{0w} \approx |\Omega_b| \]

with the abbreviations:

\[ \tilde{a} = \frac{(\gamma - 1)}{\rho} \frac{\partial \mu_{\text{turb}}}{\partial T} \]  

\[ \Gamma = \psi_{\theta} \Lambda \tilde{S}^{f_{\text{is}}}(f_{\text{d}}^0 + f_{\text{d}}^1 f_{\text{d}}^0)^n \nu - \frac{1}{\sigma} \overline{\mathbf{v} \cdot \nabla \psi_{\theta}} \]

and all partial derivatives appearing in these formulas are given in Appendix D.

The third term of Eq. (E5) is, however, written in conservative form. Hence, this part of the residual is evaluated by means of the Green–Gauss theorem as

\[ \mathbf{R}^{\text{u, coupling}}_{\text{cons}} \approx \sum_{n 
 discretized using a second-order upwind scheme with face reconstruction and limitation of gradients. This convection is also given as a nonconservative flux in the form

\[ \mathbf{R}^{\text{conv}}_{\text{cons}} = \int_{\Omega_2} \nabla \psi_{\theta} \cdot \mathbf{B}^{*} \, d\Omega \approx \sum_{n 
 approximated as

\[ \mathbf{R}^{\text{visc}}_{\text{0w}} = - \frac{1}{\sigma} \frac{\nu}{\psi_{\theta}} \mathbf{S} \]

where all the variables and the gradients of the turbulent adjoint variable, including the Weiss correction, are averaged at the cell face.

c. Source Terms Residuals. The rest of the terms in Eq. (E7) constitute the source contributions to the turbulent adjoint equation. As for the coupling residuals of the adjoint Navier–Stokes equation, the two first terms are integrated using piecewise reconstruction, resulting in a residual in the form

\[ \mathbf{R}^{\text{source}}_{p_w} \approx |\Omega_b| \left( - \psi_{\theta} B^{*} \right) \]

with \( B^{*} \) given by Eq. (D7). The \( \mathbf{E}^{*} \) term is evaluated by the Green–Gauss integral relation, yielding

\[ \mathbf{R}^{\delta, \text{source}}_{\text{cons}} \approx \sum_{n \in \Omega_b} \frac{2}{\kappa_{\rho}} \psi_{\theta} \mathbf{v} \cdot \mathbf{S} \]

4. Adjoint Eikonal Equation

As previously stated, neither the adjoint flow nor the adjoint turbulent equations depend on the adjoint distance variable \( \psi_{\theta} \). Furthermore, this adjoint variable is not needed either to compute the functional sensitivity, since typical objective functionals in aerodynamics do not depend explicitly on the distance to the surface. Hence, for the functionals considered here, there is no need to implement and numerically solve Eq. (23).

5. Boundary Conditions

Boundary conditions for a solid wall can be imposed in two ways: either by using a ghost cell scheme adapted to unstructured meshes or by directly enforcing the boundary conditions on the analytical flux expressions. On the far field, characteristic boundary conditions are used.

B. Steady-State Time Integration

A time-marching strategy in pseudotime [33,38] is used to obtain the steady solution of the flow equations and the adjoint system equations (21) and (22). Although the two sets of equations are coupled over the turbulent viscosity \( \mu_{\text{turb}} \), and it would be more efficient in terms of operation counts to formulate and solve them simultaneously, decoupling is by far the most widely used strategy, both for simplicity and because of the different character of both types of equations. In addition, it also gives flexibility in order to introduce other models of turbulence in a future.

Because of the inherent stiffness of turbulence-transport equations, time integration of both the Navier–Stokes and the Spalart–Allmaras adjoint systems is tackled with an implicit backward-Euler scheme [19]. Direct inversion of the banded matrix that defines this system is impractical because of rapid increase of operation counts with the number of mesh points and large storage requirements, especially in three dimensions. The resulting linear system is therefore solved iteratively by means of a lower–upper symmetric Gauss–Seidel algorithm [14,39]. To speed up the rate of convergence, an overset multigrid scheme has been implemented in conjunction with the solver [40,41].

C. Design Variables

In the present work, the shape functions introduced by Hicks and Henne [42] have been used as design variables for the two-
partitioning, and gradients computation] and several Python scripts. In particular, the software CADES_CFD is a finite volume code that solves the direct (flow), adjoint, and linearized problems for the potential, Euler, Navier–Stokes, and RANS equations on either 2-D or 3-D unstructured meshes using an edge-based data structure.

All terms of the turbulent adjoint formulation were implemented in the software suite with the exception of those involving the factor \( \Lambda/|\omega| \) in Eqs. (59) and (62). Numerical inspection of \( \Lambda \), given by Eq. (D12), reveals very small values for this quantity, with a fast decay outside the turbulent boundary layer. Precisely, the magnitude of the vorticity is greater close to the airfoil surface, making the whole factor \( \Lambda/|\omega| \) negligible when compared with the rest of terms of the adjoint residuals. However, neglecting these terms helps to avoid numerical instabilities far from the obstacle surface, where the magnitude of the vorticity tends to zero. Other regularization approaches for these terms are under current development.

A weighted least-squares method was used in our calculations to approximate the spatial gradients of the flow and the adjoint variables, although similar results were obtained by using the Green–Gauss formulation. Standard values for the first-, second-, and fourth-order artificial dissipation coefficients of the flow JST solver (parameters \( \kappa_0, \kappa_2, \) and \( \kappa_4 \) in [32,33]) are 0.1, 1/4, and 1/64, respectively. The value for the adjoint fourth-order artificial dissipation coefficient \( \hat{\kappa}_4 \) in Eq. (40) is taken to be 1/150. This value allows all our simulations to be numerically stable while introducing minimum artificial dissipation effects in the results. In the calibration procedure, we have used finite difference results and a grid convergence study with the adjoint Euler equations.

This section presents some numerical tests regarding the solution of the continuous turbulent adjoint problem. First, gradients computed with the new adjoint method are compared with those obtained using the so-called frozen viscosity hypothesis. This hypothesis assumes that variations of the fluid viscosity with respect to the flow variables can be neglected when compared with the rest of terms of the flow adjoint equation. Thus, the turbulence model is used to compute the flow variables, but only the adjoint equation for the mean flow is considered; that is, it solves

\[
0 = A_i^T \Psi_j
\]

subject to

\[
\Phi_i = \frac{\partial j}{\partial j_i} \quad \text{on} \ S
\]

\[
\frac{\partial j}{\partial j_i} \Psi_j = \frac{1}{g_2} \left( \frac{\partial j}{\partial T} + g_1 \cdot \Psi \right) \quad \text{on} \ S
\]

also neglecting the last term in Eq. (E4) for the computation of the adjoint operator \( A_i^T \).

Then, a transonic unconstrained drag minimization problem is shown to highlight the importance of using the complete adjoint methodology compared with the frozen viscosity strategy. Finally, an unconstrained turbulent 3-D drag minimization problem using the FFD technique will be presented to study the viability of FFD for the definition of 3-D design variables.

A. Numerical Comparison of Gradients in Drag and Lift Optimization Problems

Our first case of study involves a transonic, turbulent flow over the RAE-2822 airfoil. The flow conditions correspond to the AGARD-AR-128 case 9 [46], with corrections to account for wind-tunnel effects [47], namely, \( M_a = 0.734, \alpha = 2.54^\circ, \) and \( Re = 6.5 \times 10^6. \) Under these conditions, the flow develops a shock wave on the upper surface (located at about 50 to 60% of the airfoil chord) and a very small shock-induced separation behind the shock. The computational grid is an unstructured 2-D grid with 13,937 nodes and 22,842 elements, with 192 nodes on the airfoil surface and 40 nodes on the far-field boundary, which is located 100 chords away from the airfoil.

The Hicks–Henne functions are used as design variables in this example. The first design variable has its maximum close to the

Fig. 1 Example of FFD boxes on a DLR-F6 aircraft configuration.
trailing edge on the lower side of the airfoil, and subsequent variables displace the maximum in the clockwise direction. A total number of 38 bump functions were used, spanning the complete surface of the airfoil. Gradients computed with the two adjoint methods are compared with those obtained with a forward finite difference method. The design variable step $\delta_n$ was decreased until convergence of the finite difference gradients was achieved. In these computations, a value of $\delta_n = 10^{-8}$ was used to generate the reference gradients.

Figure 2 summarizes our main results on the comparison of gradients for the drag $c_d$ and lift $c_l$ functionals. In this figure, the negative part of the $x$ axis denotes design variables located on the lower side of the airfoil, and positive $x$ denotes those located on the upper side. Assuming the finite differences approximation as the reference solution, it is clear that the gradients computed by the turbulent adjoint method described in this paper are in much better agreement with the exact solution than those obtained using the frozen viscosity simplification. Moreover, as can be seen for both functionals, on the lower surface of the airfoil close to the trailing edge, the frozen viscosity adjoint can indeed predict a gradient not only wrong in magnitude but also in its direction, thus seriously compromising the efficiency of a gradient-based optimization solver during the minimization process.

The left panels of Fig. 3 (drag) and Fig. 4 (lift) present the convergence histories of the density-adjoint variable $\psi_1$ (left axes/solid lines) and the geometrical sensitivity parameter (right axes/dashed lines) given by the term that multiplies $\delta S$ in gradient formula equation (35) for both the turbulent and the frozen viscosity adjoint methods. Convergence improvements are especially relevant for the computation of lift gradients, although no substantial reduction in the number of iterations is obtained in this case for drag calculations. The right panels of these figures show the computed fields of the density-adjoint variable for the two methods under study. Note that,
in general, the solutions of the complete turbulent adjoint are somehow less affected by the presence of the shock wave. The same applies for the rest of adjoint flow variables.

**B. Two-Dimensional Unconstrained Drag Minimization Using Adjoint Reynolds-Averaged Navier–Stokes**

The goal of this academic problem is to reduce the drag of the RAE-2822 profile by means of modifications of its surface. The angle of attack, Mach number, and Reynolds number are kept fixed so that the flow remains transonic ($M_\infty = 0.734$, $\alpha = 2.54^\circ$, and $Re = 6.5 \times 10^4$). The same set of 38 Hicks–Henne functions defined in the previous section has been used here as design variables.

The convergence of the optimization process is presented in the left panel of Fig. 5. As expected, gradients computed with the complete adjoint Spalart–Allmaras formulation provide an airfoil with a lower value of drag coefficient than using the frozen viscosity gradients (note the nonoptimal pressure distribution of the trailing edge due to the erroneous frozen viscosity gradient at that location). The initial pressure distribution and the optimized one with the Spalart–Allmaras adjoint method are shown on the right panel of this figure.

**Fig. 4** Comparison between the turbulent and the frozen viscosity adjoint methods in the computation of lift sensitivities.

**Fig. 5** Unconstraint drag minimization of a RAE-2822 airfoil (transonic flow modeled by the RANS equations).

**Fig. 6** Pressure coefficient distribution of the ONERA-M6 wing and control points of the FFD box (white points are design variables).
C. Three-Dimensional Unconstrained Drag Minimization Using Adjoint Reynolds-Averaged Navier–Stokes and Freeform Deformation

The objective of our last numerical test is to check the performance of the developed methodology in conjunction with the FFD approach for the definition of 3-D design variables. A single-point minimization case is used to study the new continuous adjoint method for turbulent flows. The selected flow conditions were \( M_{\infty} = 0.8395 \), \( \alpha = 3.06^\circ \), and \( Re = 11.72 \times 10^6 \), and the aerodynamic profile was an ONERA-M6 wing (43,008 hexahedron elements). Only the upper surface of the wing will be redesigned in this case. A total number of 12 control points are used as design variables (see white points in Fig. 6), employing Bernstein polynomials of the sixth, fifth, and second orders in the \( x, y \), and \( z \) directions, respectively.

To determine convergence, the drag and the sensitivity coefficients were monitored on the surface of the wing profile. A Cauchy’s convergence criteria for series in both coefficients (no changes in their sixth decimal place during 100 iterations) was used as stopping criteria in this example. The entire design process (12 optimization iterations) was performed overnight using a personal laptop (2.53 GHz Intel Core 2 Duo).

Figure 7 (left) shows a comparison of the optimization convergence history between the frozen viscosity strategy and the complete adjoint formulation for our 3-D case of study. Note that the frozen viscosity strategy does not result into any design improvement after the fourth iteration of the optimization process, achieving only a 5% drag reduction. On the other hand, after 10 iterations of the complete turbulent adjoint method, the drag coefficient is finally reduced a total of 10%. The right panel of the same figure also shows the pressure coefficient distribution of the original ONERA-M6 wing compared with the redesigned profile using the complete Spalart–Allmaras adjoint formulation. The shock wave initially present on its upper surface has been clearly diminished in the redesigned airfoil.

Hence, this optimal design test proves the flexibility of the continuous adjoint approach in 3-D applications, combined with a FFD technique for mesh deformation and an algebraic method [38] for the displacement of a high-stretching grid.

Fig. 7 Optimization convergence history, turbulent adjoint method vs frozen viscosity (left). Pressure coefficient distribution of the initial and redesigned ONERA-M6 airfoil (right).

VI. Conclusions

In this work, the continuous adjoint Spalart–Allmaras approach to aerodynamic design optimization has been presented. The Spalart–Allmaras model has been chosen in order to describe turbulence phenomena due to its wide use in industrial applications of aerodynamics. However, the framework presented here for the turbulent continuous adjoint approach is general, and it can be easily extended to incorporate other models of turbulence, such as \( k-\varepsilon \), \( k-\omega \), or shear stress models. The resulting formulation does not need the computation of second-order derivatives of the flow variables, and once the adjoint variables have been computed, it only requires an integration on the surface of the aerodynamical body in order to evaluate the gradient of the functional of interest under deformations of the body surface.

The accuracy of the sensitivity derivatives that result from the application of the new method has been assessed by comparison with finite difference computations, which illustrate the importance of the complete formulation instead of the frozen viscosity strategy. This improvement in the quality of the computed gradients is also clearly translated into the optimization process, with the complete turbulent adjoint being able to produce better optimized profiles than those obtained using frozen viscosity. Finally, a 3-D test case, making use of a combination of the continuous adjoint approach with advanced freeform techniques for mesh deformation, has also been presented, thus highlighting the potential flexibility of the continuous adjoint approach in realistic 3-D industrial applications.

The results presented here are very promising, but further numerical tests are still necessary in order to face the industrialization of the complete continuous adjoint methodology. In particular, the optimization of full complex 3-D configurations and convergence improvements are open research topics that have to be addressed.

Appendix A. Navier–Stokes Equations

As usual in the Navier–Stokes equations, system equation (1) separately considers the convective terms, denoted by \( F^c \), and the viscous ones, denoted here by \( F^{v^2} \) and \( F^{v^1} \). They are given by

\[
F_i^c = \begin{bmatrix}
\rho v_i \\ \rho v_i v_1 + P \delta_{i1} \\ \rho v_i v_2 + P \delta_{i2} \\ \rho v_i v_3 + P \delta_{i3} \\ \rho v_i H \\
\end{bmatrix}, \quad F_i^{v^1} = \begin{bmatrix}
\tau_{i1} \\ \tau_{i2} \\ \tau_{i3} \\
\end{bmatrix}, \quad F_i^{v^2} = \begin{bmatrix}
C_p \delta_i T \\
\end{bmatrix} \quad i = 1, \ldots, 3
\]

where \( v_i \) are the Cartesian velocity components, \( H \) is the fluid enthalpy, \( \delta_{ij} \) is the Kronecker delta function, and \( \tau_{ij} = \partial_j v_i + \partial_i v_j - \tfrac{2}{3} \delta_{ij} \nabla \cdot \mathbf{v} \). Recall that Latin indexes \( i, j \) denote 3-D Cartesian coordinates, with repeated indexes implying summation. In these formulas, \( C_p \) is the specific heat at constant pressure, \( T = P/\rho R \) is the temperature, and \( R \) is the gas constant, so that, for an ideal gas, \( C_p/R = \gamma/(\gamma - 1) \), with \( \gamma \) constant. To close the system, the
dynamic viscosity is assumed to satisfy Sutherland’s law, \( \mu_{\text{dyn}} = \mu_1 T^{1/2}/(T + \mu_2) \), where \( \mu_1 \) and \( \mu_2 \) are also specified constants.

**Appendix B. Spalart–Allmaras Turbulence Model**

In Eq. (2), we have considered a general framework for a one-equation turbulence model. Here, we focus on the Spalart–Allmaras model, for which explicit formulas for the adjoint formulation are obtained below. In this case, the turbulent viscosity is computed as

\[
\mu_{\text{tur}} = \rho \hat{\nu} f_{\nu 1}, \quad f_{\nu 1} = \frac{\chi^3}{\chi^3 + c_{\nu 1}}, \quad \chi = \frac{\hat{\nu}}{\nu}, \quad \nu = \frac{\mu_{\text{dyn}}}{\rho}
\]

(B1)

The new variable \( \hat{\nu} \) is obtained by solving Eq. (2) with

\[
T^{\nu}(U, \hat{\nu}) = -\frac{\nu + \hat{\nu}}{\sigma} \nabla \hat{\nu} + \nu \hat{\nu}
\]

(B2)

\[
T^{\nu}(U, \hat{\nu}, d_3) = c_{\nu 1} S \hat{\nu} - c_{\nu 1} f_{\nu 1} \left( \frac{\hat{\nu}}{d_3} \right)^2 + \frac{c_{\nu 3}}{\sigma} |\nabla \hat{\nu}|^2
\]

(B3)

where the production term \( S \) in Eq. (B3) is defined as \( S = [\omega + (\hat{\nu}/\kappa d_3^2)] f_w \), \( \omega = \nabla \times \mathbf{v} \) is the fluid vorticity, \( d_3 \) is the distance to the nearest cell, and \( f_{\nu 1} = 1 - \chi/(1 + x^2 d_3) \). The function \( f_w \) in Eq. (B3) is computed as \( f_w = g(1 + c_{\nu 3})/(g^3 + c_{\nu 3}) \), where \( g = r + c_{\nu 3} r^3 - r = \hat{\nu}/\kappa d_3^2 \).

Finally, the set of closure constants for the model is given by:

- \( c_{\nu 1} = 0.1355 \), \( c_{\nu 2} = 0.622 \), \( \kappa = 0.41 \), \( c_{\nu 3} = \langle c_{\nu 3}^2 \rangle /
\]

where \( \langle c_{\nu 3}^2 \rangle \), \( c_{\nu 2} = 0.3 \), \( c_{\nu 3} = 2.1 \), and \( \nu = 7.1 \)

**Appendix C. Linearized Navier–Stokes Equations**

In this appendix, we compute \( \partial R_U/\partial U \) and \( \partial R_U/\partial \hat{\nu} \) in Eq. (14):

\[
\frac{\partial R_U}{\partial U} = \nabla (A^c \delta U) - \nabla \left( F^c \frac{\partial \mu_{\text{dyn}}}{\partial U} + \mu_{\text{tot}} A^{\text{tot}} \delta U \right)
\]

\[
+ \mu_{\text{tot}} D^{\text{tot}} \nabla \delta U \right)
\]

(C1)

\[
\frac{\partial R_U}{\partial \hat{\nu}} = -\nabla \left( F^c \frac{\partial \mu_{\text{dyn}}}{\partial \hat{\nu}} \right)
\]

(C2)

where

\[
\frac{\partial \mu_{\text{tot}}}{\partial U} = \frac{\partial \mu_{\text{dyn}}}{\partial U} + \frac{\partial \mu_{\text{tur}}}{\partial U}, \quad \frac{\partial \mu_{\text{tot}}^2}{\partial U} = P_{\text{ra}} \frac{\partial \mu_{\text{dyn}}}{\partial U} + \frac{1}{P_{\text{ra}}} \frac{\partial \mu_{\text{tur}}}{\partial U}
\]

and

\[
\frac{\partial \mu_{\text{dyn}}}{\partial T} = \frac{\partial \mu_{\text{dyn}}}{\partial T} = \frac{\partial \mu_{\text{dyn}}}{\partial T} = \frac{\partial \mu_{\text{dyn}}}{\partial T} = \frac{3 \mu_2}{2(T + \mu_2)}
\]

(C3)

\[
\frac{\partial \mu_{\text{tur}}}{\partial \hat{\nu}} = \nu f_{\nu 1} \left( 1 + \frac{3 c_{\nu 3}^3}{\kappa^3 + c_{\nu 3}} \right) \frac{\partial \rho}{\partial \hat{\nu}} - \chi f_{\nu 1} \frac{3 c_{\nu 3}^3}{\kappa^3 + c_{\nu 3}} \frac{\partial \mu_{\text{dyn}}}{\partial \hat{\nu}}
\]

(C4)

\[
\frac{\partial \mu_{\text{tur}}}{\partial \hat{\nu}} = \rho f_{\nu 1} \left( 1 + \frac{3 c_{\nu 3}^3}{\kappa^3 + c_{\nu 3}} \right)
\]

(C5)

with

\[
\frac{\partial T}{\partial \hat{\nu}} = \frac{(\gamma - 1)}{R \rho} (|\mathbf{v}|^2 - E, -e_1, -e_2, -e_3, 1)
\]

and \( \partial \rho/\partial U = (1, 0, 0, 0, 0) \).

In Eq. (C1), we have

\[
A^c = (A^c_1, A^c_2, A^c_3), \quad A^c_i = \frac{\partial A^c}{\partial U} \bigg|_{U=(\gamma-1)}
\]

\[
A^{\text{tot}} = (A^{\text{tot}}_1, A^{\text{tot}}_2, A^{\text{tot}}_3), \quad A^{\text{tot}}_i = \frac{\partial A^{\text{tot}}}{\partial U} \bigg|_{U=(\gamma-1)}
\]

\[
D^{\text{tot}} = \left( D^{\text{tot}}_{11} D^{\text{tot}}_{12} D^{\text{tot}}_{13} D^{\text{tot}}_{21} D^{\text{tot}}_{22} D^{\text{tot}}_{23} D^{\text{tot}}_{31} D^{\text{tot}}_{32} D^{\text{tot}}_{33} \right), \quad D^{\text{tot}}_{ij} = \frac{\partial D^{\text{tot}}}{\partial U} \bigg|_{U=(\gamma-1)}
\]

\[
i, j = 1 \ldots 3, \quad k = 1, 2
\]

Defining for convenience, \( a_0 = (\gamma - 1) \) and \( \phi = (\gamma - 1)(|\mathbf{v}|^2/2) \); then, we have

\[
A^c_1 = \left( \begin{array}{cccccc}
0 & -v_1 c_{\nu 1} & v_1 (a_0 - 1) v_i c_{\nu 1} & v_i c_{\nu 1} & v_i c_{\nu 1} & v_i c_{\nu 1} \\
-v_1 c_{\nu 1} & 0 & -v_1 c_{\nu 1} & v_1 (a_0 - 1) v_i c_{\nu 1} & v_i c_{\nu 1} & v_i c_{\nu 1} \\
v_1 (a_0 - 1) v_i c_{\nu 1} & -v_1 c_{\nu 1} & 0 & -v_1 c_{\nu 1} & v_1 (a_0 - 1) v_i c_{\nu 1} & v_i c_{\nu 1} \\
v_i c_{\nu 1} & v_i c_{\nu 1} & v_i c_{\nu 1} & 0 & -v_1 c_{\nu 1} & v_i c_{\nu 1} \\
v_i c_{\nu 1} & v_i c_{\nu 1} & v_i c_{\nu 1} & v_i c_{\nu 1} & 0 & -v_1 c_{\nu 1} \\
v_i c_{\nu 1} & v_i c_{\nu 1} & v_i c_{\nu 1} & v_i c_{\nu 1} & v_i c_{\nu 1} & 0
\end{array} \right)
\]

\[
A^{\text{tot}}_1 = \left( \begin{array}{cccccc}
0 & -v_1 c_{\nu 1} & v_1 (a_0 - 1) v_i c_{\nu 1} & v_i c_{\nu 1} & v_i c_{\nu 1} & v_i c_{\nu 1} \\
-v_1 c_{\nu 1} & 0 & -v_1 c_{\nu 1} & v_1 (a_0 - 1) v_i c_{\nu 1} & v_i c_{\nu 1} & v_i c_{\nu 1} \\
v_1 (a_0 - 1) v_i c_{\nu 1} & -v_1 c_{\nu 1} & 0 & -v_1 c_{\nu 1} & v_1 (a_0 - 1) v_i c_{\nu 1} & v_i c_{\nu 1} \\
v_i c_{\nu 1} & v_i c_{\nu 1} & v_i c_{\nu 1} & 0 & -v_1 c_{\nu 1} & v_i c_{\nu 1} \\
v_i c_{\nu 1} & v_i c_{\nu 1} & v_i c_{\nu 1} & v_i c_{\nu 1} & 0 & -v_1 c_{\nu 1} \\
v_i c_{\nu 1} & v_i c_{\nu 1} & v_i c_{\nu 1} & v_i c_{\nu 1} & v_i c_{\nu 1} & 0
\end{array} \right)
\]
where tensors $\tilde{n}$, $\tilde{\pi}$, and $\tilde{\zeta}$ in the definition of $A^{i,j}$ are given by

$$
\eta_{ij} = \partial_j \left( \frac{v_i}{\rho} \right) + \partial_i \left( \frac{v_i}{\rho} \right) - \frac{2}{3} \delta_{ij} \nabla \cdot \left( \frac{v}{\rho} \right)
$$

$$
\pi_{ij} = v_j \partial_i \left( \frac{1}{\rho} \right) + v_i \partial_j \left( \frac{1}{\rho} \right) - \frac{2}{3} \delta_{ij} \nabla \cdot \left( \frac{1}{\rho} \right) = \eta_{ij} - \frac{1}{\rho} \tau_{ij}
$$

$$
\zeta_{ij} = v_i \partial_j \left( \frac{1}{\rho} \right) - v_j \partial_i \left( \frac{1}{\rho} \right) + \frac{1}{3} v_i \partial_j \left( \frac{1}{\rho} \right)
$$

### Appendix D. Linearized Spalart–Allmaras Turbulence Model

Here, we compute the terms corresponding to linearized turbulence equation (15). Note that

$$
\frac{\partial R_c}{\partial U} \delta U = \nabla \cdot (F^{cv} \delta U) - F^{i} \delta U - \mathbf{M}^{c} \nabla \delta U \tag{D1}
$$

$$
\frac{\partial R_s}{\partial \mathbf{b}} \delta \mathbf{b} = -K^{s} \delta \mathbf{b} \tag{D2}
$$

where $\mathbf{M}' = (M'_1, M'_2, M'_3)$, $E'^s = (\mathbf{E}'_1, \mathbf{E}'_2, \mathbf{E}'_3)$, and $E' = (E'_1, E'_2, E'_3)$.

The Jacobian matrices associated to the convective/viscous flux are given by

$$
\mathbf{B}^{cv} = \frac{\partial \mathbf{T}^{cv}}{\partial \mathbf{b}} = -\frac{\nabla \hat{\mathbf{b}}}{\sigma} + \mathbf{v} \tag{D4}
$$

$$
\mathbf{E}' = \frac{\partial \mathbf{E}'}{\partial \mathbf{U}} = -v + \hat{\mathbf{v}} \tag{D5}
$$

$$
\mathbf{F}^{cv} = \frac{\partial \mathbf{T}^{cv}}{\partial \mathbf{U}} = \alpha \left( \frac{\partial \mathbf{T}}{\partial \mathbf{U}} \right)^T \nabla \hat{\mathbf{b}} + \left( \frac{\mu_{S}}{\sigma \rho} \nabla \hat{\mathbf{b}} - \nabla \hat{\mathbf{b}} \right) \mathbf{I}_3 \tag{D6}
$$

$$
\alpha = -\frac{1}{\rho} \frac{\partial \mathbf{S}}{\partial \mathbf{b}} \frac{\partial \mathbf{T}}{\partial \mathbf{U}} \tag{D7}
$$

Here, $\partial \mathbf{S} / \partial \mathbf{b}$ and $\partial \mathbf{T} / \partial \mathbf{U}$ are given in Appendix C, and $\mathbf{I}_3$ is the $3 \times 3$ identity matrix.

Concerning the derivatives of the source term $T^s$, we have

$$
B^s = \frac{\partial T^s}{\partial \mathbf{b}} = \left( c_{b1} \hat{S} - 2 c_{w} f_w \frac{\hat{\mathbf{b}}}{d_s} \right) - c_{w} \left( \frac{\hat{\mathbf{b}}}{d_s} \right)^2 f_{w} \mathbf{g}^T \mathbf{r}^s
$$

$$
+ \Lambda \left( \hat{S}^{s} f_{w} f_{w}^{s} + f_{w}^{s} f_{w}^{s} \right) \mathbf{b} + \hat{S}^{s} \tag{D8}
$$

$$
F^s = \frac{\partial T^s}{\partial \mathbf{U}} = \mathbf{L} \left[ \hat{S}^{s} f_{w} f_{w}^{s} + f_{w}^{s} f_{w}^{s} \right] \mathbf{b} \left( \frac{\hat{\mathbf{b}}}{d_s} \frac{\partial \mathbf{T}}{\partial \mathbf{U}} + \frac{\partial \mathbf{S}}{\partial \mathbf{U}} \frac{\partial \mathbf{U}}{\partial \mathbf{U}} \right)^T \tag{D9}
$$

$$
E^s = \frac{\partial T^s}{\partial \mathbf{b}} = \frac{2 c_{b2}}{\sigma} \frac{\partial \mathbf{b}}{d_s} \tag{D10}
$$

$$
M^s = \frac{\partial T^s}{\partial \mathbf{b}} \frac{\partial \mathbf{U}}{\partial \mathbf{b}} = \frac{1}{|\mathbf{b}|} \mathbf{L} \left( \frac{\mathbf{b}}{d_s} \mathbf{b} - \mathbf{S} \right) \cdot \mathbf{N} \tag{D11}
$$

with

$$
\mathbf{L} = \frac{\partial T^s}{\partial \mathbf{b}} = c_{b1} \hat{\mathbf{b}} - c_{w} \left( \frac{\hat{\mathbf{b}}}{d_s} \right)^2 f_{w} \mathbf{g}^T \mathbf{r}^s \tag{D12}
$$

and where $\mathbf{N}$ in Eqs. (D8) and (D11) is the $3 \times 5$ matrix defined by $\delta \mathbf{b} = N \delta \mathbf{U}$; that is,

$$
\mathbf{N} = \frac{1}{\rho} \left( \begin{array}{ccccc} -v_1 & 1 & \cdots & \cdots & \cdots \\ -v_2 & \cdots & 1 & \cdots & \cdots \\ \vdots & & & \ddots & \vdots \\ -v_3 & \cdots & \cdots & & 1 \end{array} \right) \tag{D13}
$$

Finally, the whole set of partial derivatives needed to compute Eqs. (D7–D12) reads
Appendix E. Adjoint Formulas

In this appendix, we give explicit formulas for the adjoint operators and boundary conditions. These are obtained from identity equation (17), which is deduced from the following integration by parts:

$$
\int_{\Omega} \psi_T \frac{\partial R_T}{\partial U} dU + \frac{\partial R_T}{\partial \psi} d\delta = \int_{\Omega} (A_{ij}^T \psi_T) T dU + \int_{\Omega} A_{ij}^T \psi_T d\delta
$$

$$
- \int_S \nabla \cdot (\delta P n - \delta n \cdot \psi) - \int_S (g_i \cdot \nabla + g_2 \partial_2 \psi_3) S T - \int S h S
$$

(E1)

where we have used \( \partial_2 dS = -1 \). Here, domain integrals on the right-hand side contain the adjoint operators, given by

$$
A_{ij}^T \psi_T = - \nabla \Psi_T \cdot A^* - \nabla \cdot (\Psi_T^* \cdot \mu_{stot}^T D^*)
$$

$$
+ \nabla \Psi_T^* \cdot \mu_{tot}^T D^* + \nabla \Psi_T \cdot \frac{\partial \mu_{tot}}{\partial U}
$$

(E4)

$$
A_{ij}^T \psi_0 = - \nabla \psi_0 \cdot F^* - \psi_i F_j^* + \nabla \cdot (\psi_i M^*)
$$

(E5)

$$
A_{ij}^T \psi_U = \Psi_T^* \cdot F^* \frac{\partial \mu_{tot}}{\partial U}
$$

(E6)

$$
A_{ij}^T \psi_B = - \nabla \psi_0 \cdot B^* + \nabla \cdot (\nabla \psi_0 \cdot E^*) - \psi_i B^j + \nabla \cdot (\psi_i E^*)
$$

(E7)

$$
A_{ij}^T \psi_u = - K^* \psi_0
$$

(E8)

The terms \( g_1, g_2, g_3, g_4, g_5, \) and \( h \) appearing in the boundary integrals in Eqs. (E1–E3) are given by

$$
g_1 = \frac{\partial \mu_{tot}}{\partial \psi} n \cdot \tilde{r}
$$

$$
g_2 = C_r \mu_{tot}, \quad g_3 = \frac{v}{\sigma}
$$

$$
g_4 = \frac{\partial \psi_u}{\partial \sigma \psi} \left( 1 + \frac{\psi_u}{\psi} \right) T + \frac{\partial \mu_{tot}}{\partial \psi}
$$

(E10)

$$
h = - (\rho \psi_1 + \rho H \psi_3) (\delta_0 \psi_0 + \psi_0 \nabla \cdot \sigma \cdot \delta_0 - \nabla \cdot \delta \nabla \psi_0)
$$

$$
- \psi_0 \sigma : \nabla \psi + \mu_{tot}^T C_{\rho} \nabla \sigma \psi_0 \cdot \nabla \tilde{S} + \partial_2 \tilde{S} (\nabla \cdot \tilde{\sigma} \cdot \psi_0)
$$

(E11)

where \( \tilde{S} \cdot \nabla \psi = \sigma_i \partial_i \psi, \) with

$$
\tilde{S} = \mu_{tot}^T (\nabla \psi + \nabla \psi^T - I) \nabla \psi
$$

Some of the terms in \( h \) above can be simplified. In particular, taking into account that \( \psi = 0 \) and \( \nabla \psi = 0 \) on the obstacle surface, we have \( \nabla \psi = \partial_2 \psi = \partial_3 \psi = 0 \) on \( S \). Hence,

$$
\sigma \cdot \nabla \psi = \sigma_i \partial_i \psi = \partial_2 \psi = \partial_3 \psi = 0 \text{ on } S
$$

and the second and fourth terms in Eq. (E11) cancel.

On the other hand, the continuity equation yields \( \nabla \cdot \psi = 0 \) on \( S \). Hence,

$$
0 = \nabla \cdot \psi = \partial_2 \psi = \partial_3 \psi = \partial_3 \psi = 0 \text{ on } S
$$

and the first term in Eq. (E11) also cancels.

In the same way, one may also notice that \( \partial \mu_{tot}/\partial \tilde{S} = 0 \) on \( S \), since \( f_{st} = 0 \) on the obstacle surface. Thus, the term \( h \) reads

$$
h = - \nabla \cdot \tilde{S} \cdot \delta_0 \cdot \nabla \psi + \mu_{tot}^T C_{\rho} \nabla \sigma \psi_0 \cdot \nabla \tilde{S} + \partial_2 \tilde{S} \cdot (\nabla \cdot \tilde{\sigma} \cdot \psi_0)
$$

(E12)

Finally, adding the three terms in Eqs. (E1–E3), we easily obtain Eq. (17) with

$$
\hat{g} = h = - \frac{1}{\sigma} \frac{\partial \psi_u}{\partial \sigma \psi} \psi_0
$$

(E13)
